DIAGNOSTIC IMAGING REPORT

Patient	DOB	Study Date	Accession	Ordering Physician
Turner, Megan E.	06/06/1952	October 9, 2024	LRA-2024-8847	Steven Alford, MD

EXAMINATION

X-Ray, Both Knees: AP, lateral, and Merchant views, bilateral

CLINICAL INDICATION

Bilateral knee pain, worse with walking and stair climbing, limiting ambulation to 10-15 minutes on flat terrain. Known osteoarthritis, progressive since 2015. Evaluate current status for clinical decision-making regarding knee replacement.

FINDINGS

RIGHT KNEE: Moderate to severe tricompartmental osteoarthritis. Joint space narrowing most pronounced in the medial compartment, estimated 70-75% reduction from normal. Subchondral sclerosis and cyst formation present. Osteophyte formation at the tibial and femoral margins. No acute fracture.

LEFT KNEE: Moderate osteoarthritis. Medial compartment narrowing approximately 50-60% of normal. Subchondral sclerosis without cyst formation. Moderate osteophyte formation. No acute fracture.

BILATERAL: No loose bodies identified. Patellofemoral compartment shows moderate joint space narrowing bilaterally. Soft tissue swelling consistent with chronic degenerative joint disease.

IMPRESSION

- Moderate to severe osteoarthritis, right knee, tricompartmental, with predominant medial compartment involvement.
- Moderate osteoarthritis, left knee.
- Findings correlate with clinical history and reported functional limitation.
- Imaging consistent with candidacy for total knee arthroplasty (TKR) if patient desires surgical management.

Note: Patient has declined surgical consultation at this time per Dr. Alford's visit notes of October 2024.
