

WASATCH IMAGING CENTER
Radiology Report

Patient: Amanda Hayes

DOB: 01/19/1985

MRN: WIC-0773312

Referring Provider: Nathan Gibbs, MD, Sugarhouse Family Medicine

Exam Date: April 12, 2022

Exam: MRI Lumbar Spine without contrast

CLINICAL HISTORY

41-year-old patient with several weeks of low back pain radiating into the left leg following a lifting strain. Evaluate for disc pathology.

TECHNIQUE

Multiplanar, multisequence MRI of the lumbar spine performed without intravenous contrast on a 1.5T magnet.

FINDINGS

Alignment is normal. Vertebral body heights are preserved. Conus terminates normally. Levels L1-L2 through L3-L4 are unremarkable.

L4-L5: There is a left paracentral disc herniation measuring about 6 mm, producing mild to moderate narrowing of the left lateral recess and contact with the descending left L5 nerve root. No high-grade central canal stenosis.

L5-S1: Mild disc desiccation without significant herniation or stenosis.

IMPRESSION

1. Left paracentral L4-L5 disc herniation with contact on the descending left L5 nerve root, correlating with the patient's left leg symptoms.
2. Otherwise mild degenerative changes appropriate for age.

Recommend conservative management with physical therapy and clinical correlation. Electrodiagnostic study only if symptoms progress.
